A recent paper [J. Opt. Soc. Am. B 24, 1633 (2007)] reports the gain and sensitivity of a time-resolved fluorescence spectrometer based on parametric amplification. We question the claimed detection limit and explanation for the unusual temporal shape of the measured signal at very low levels of fluorescence. We provide an alternative explanation for the observations. Several other points are also clarified. © 2008 Optical Society of America

posted August 7, 2008 (Doc. ID 95343); published September 12, 2008

A backward fluorescence collection method is employed in a noncollinear optical parametric amplification-gated femtosecond time-resolved fluorescence spectrometer to determine the detection limit of this recently developed technique. In this way the supercontinuum generation that interferes with the determination of the detection limit is completely excluded, and the achieved upper limit of the detectable photon number with the 150 fs gating pulse is approximately 19. © 2008 Optical Society of America

ALL-OPTICAL SWITCHING  
Single-photon power

*Appl. Phys. Lett.* **92**, 151109 (2008)

All-optical switching has the potential to offer ultrafast switching speeds that are not subject to conventional electronic limitations, and could help revolutionize communication and information processing. Researchers in China have now demonstrated an all-optical switch based on three-wave-mixing parametric amplification in a nonlinear crystal.

The idea underlying the scheme involves using a weak beam of light to turn a stronger beam of light on and off. This is essential for cascaded classical and quantum computation elements. Although the concept has already been demonstrated using four-wave mixing, Xiao-Feng Han and colleagues present an approach based on three-wave-mixing optical parametric amplification in a nonlinear crystal. Using a beta barium borate crystal as the core switching element, they show that a beam containing single photons (with an average of 0.75 photons per pulse) can be used to turn a beam containing up to  $5.9 \times 10^8$  photons on and off. The switching can be performed within 400 fs. Analysis of the on/off states shows that they are well defined and that the switch has a broad bandwidth of 10 nm (or 5 THz).
